The value of sugar-beet cake as a fertilizer. *Agri...*
Zucker. Monographien Kautschuk (9, 207-17(1917))...
 Cakes and shreds were used in a 3:1 ratio. Cakes were more
 effective than any of the fertilizers or manure, with a slight-
 ly better effect when applied in the fall. Probably the
 nitrification is more rapid when cake is used. The change
 of nitrification seems to correspond to the rate of N as-
 similation of the plant while with sol. N fertilizers losses
 may occur during the same period. S. B. de Pinsky

SOURCE: Documentary: Newsletter, Issue No. 2, issued by the Center for Documentation and Communication Research, School of Library Science, Western Reserve University, Cleveland 6, Ohio.

1. To date, 49 papers, from 10 countries, have been scheduled for the subject Conference. They include:

- ACHEVOVA, J.S., Linguistics Institute, USSR Academy of Sciences, Moscow - "Common machine languages as 'auxiliary codes' for 'mediator languages'."
- ARMSTRONG, R.D., Experimental Laboratory of Machine Translation, Leningrad University - (1) "Report on the activities of the experimental laboratory of machine translation (Leningrad University)" (2) "Universal code of sciences and machine languages."
- CHERNIL, V. P., LAYNEV, YEN, G. A., and KUDKOVA, E. V., Institute of Scientific Information, USSR Academy of Sciences, Moscow - "Experimental information language for mechanical translation of scientific and technical literature."
- SHCHERBA, A. M., and TERNOSTEV, A. P., Moscow State University - "Chemical nomenclature translation."

Report to be submitted for the Intl. Conference on Machine Searching and Translation, (for Standards on a Common Language), Cleveland, Ohio, 6-13 September 1979.

Fractional salting out in the refined gravimetric modification for the study of the colloidal properties of vegetable tanning liquors and extracts. M. KOTOV AND B. ZUCKERMAN. *Vysokh Kachestvennoi Prom. Torgov.* 1929, 40-50; *Chem. Zvest.* 1936, 11, 3685-6. The following procedure is suggested: salting out by the Stanny method, filtration through a glass plate or asbestos-covered Gooch crucible, washing of the ppt. on the filter with NaCl soln. of the same concn. as that of the salting out soln., soln. of

the ppt. on the filter in water of 60-70° with addn. of NH_3 , treatment with HNO_3 , heating and detn. of the NaCl by the Volhard method. ALFRED PINSON

2230. CHARACTERISTICS OF THE FOCAL CONVULSIVE SEIZURE INDUCED BY STIMULATION OF DIFFERENT CORTICAL LAYERS - Caracteristicile accesului convulsiv focal declanșat prin excitarea unor straturi corticale diverse - Zuckerman E. Inst. de Neurol. 'I. P. Pavlov', București - REV. FIZIOL. NORM. PATOL. 1957, 4/5 (240-244) Graphs 1

Two pairs of electrodes (each of 100 μ .) were implanted chronically at 2 symmetrical points of the cerebral cortex in 40 rats. In 15 rats the 2 electrode pairs were of the same length and thus stimulated the same cortical layer; in the other 25 they were of different lengths and thus ended in different layers. (The placing was subsequently verified histologically.) When electrical stimuli of increasing intensity were applied until convulsive activity appeared, it was found that the convulsion threshold for 2 symmetrical points was the same if the electrodes were in the same layer, but when the electrodes were in 2 different layers the threshold for the superficial layers was much higher than that for the deeper layers (V and VI). This is not an exclusively motor phenomenon of the pyramidal cells, as in the classical experiments of Dusser de Barenne, but a central phenomenon characterized by the appearance of a hypersynchronous bioelectrical activity due to the formation of convulsive neuronal chains.

Graur - Bucharest

the above

Radiography of explosion and detonation processes. V. A. Zuber-
man (Compt. rend. Acad. Sci. U.R.S.S., 1943, 68, 247-249). The
phenomena which occur inside the explosive and in its immediate
neighbourhood on detonation have been studied by means of a high
speed radiographic method. X-Ray flashes of duration 10⁻⁸ sec
were used in the investigation. Limitation of the intensity of the
spark made it impossible to examine explosives containing heavy
atoms. For these experiments tetryl has been used, Hg fulminate
being the initiator. By making use of the shock wave it was possible
to obtain exact coincidence between the explosion and the X-ray
flash. A second radiograph, taken after a very short time interval,
enabled the velocities of the various portions of the explosive charge
to be determined.

Title : Thiamine and Riboflavin Urinary Excretion as an Index
of Saturation of the Human Organism with These Vitamins

Orig Pub : Roczn. Panstw. zakl. hig., 1956, 7, No 3, 223-239

Abstract : Thiamine (T) and riboflavin (R) excretion was determined
in 70 people between the ages of 15 and 58. With a daily
dose of 1.5 mg. of T and 2 mg. of R (an adequate daily
dose), there was a daily excretion of about 70 mcg. of T
and 450 mcg. of R. T and R administration on an empty
stomach fluctuated within the first hour between 5 - 15
mcg. of T and 14 - 30 mcg. of R. With a sufficiently large
dose of vitamins, a definite relationship between the
utilization of vitamins and excretion was established. The

latter emphasize the usefulness of this determination in the evaluation of the saturation of the organism with T and R. After 4 hours of 5 mg. of T and R administration, the excreted vitamins were 100 and 500 mcg., respectively. The author proposes that for a correct picture of the vitamin saturation in the body, it is sufficient to take samples after 4 hours for the determination of T and R in the urine. -- G. A. Cherkos

TOPIC TAGS: measuring apparatus, measuring instrument, measurement, control circuit, electric current, electric switch, electronic switch, electronics

TRANSLATION: The connection of a measuring device for measuring tolerance in particular, designated for use in programmed control equipment, has the measured quantities converted to voltage values or the current measurement transferred in the form of an electric code used for actuating the signal number table and for other evaluations with a metering switch that is equipped for actuating the switch and for comparing the deviations with the reference voltage source. In the course of operation, the installed switch is actuated by a signal from the comparison of the measuring device so that the reference voltage supplied to the comparison element is as high as the voltage supplied from the input of the measuring device or proportional to it and a change in the position of the metering switch is accompanied by a change in the point of the reference voltage value, or of the value of the voltage supplied from the input of the measuring

AUTHOR: Zudakin, A.I.

TITLE: Use of White Noise for Measurement of Interference in the Telephone Channels of Radio-relay Lines (Ispol'zovaniye belogo shuma dlya izmereniya pomekh, voznikayushchikh v telefonnykh kanalakh radioreleynykh liniy)

PERIODICAL: Elektrosvyaz', 1959, Nr 4, pp 56 - 63 (USSR)

ABSTRACT: After reviewing the internationally recommended noise limits, the author points out that, up to the present time, there is no agreed definition of mean power of a multi-channel signal; for more than 240 channels, the mean power is defined by Eq (1) and for more than 12, but less than 240 channels by Eq (2). Recently both in Russia and in other countries, methods of noise measurement have been developed which are based on the replacement of the multi-channel signal by white noise. This is permissible because the multi-channel signal, being composed of independent, random signals has a white-noise probability distribution.

Figure 1 shows the simplified block diagram of apparatus, designed to measure the relative noise power levels, i.e. the value of the increase of white noise power in a small

Card1/5

SOV/106-59-4-7/13

Use of White Noise for Measurement of Interference in the Telephone Channels of Radio-relay Lines

frequency band within the limits of the linear spectrum over the noise power produced by the transmission element under test. The apparatus consists of two parts, a transmitter and a receiver, between which the element under test is connected.

The main elements of the transmitter are (Figure 2): a source of white noise, which simulates the multi-channel signal; a broad-band amplifier; blocking filters. The amplifier has a bandwidth equal to the linear spectrum of the multi-channel signal and the blocking filters are designed to suppress a small band of frequencies within which the measurements are made. At the output of the transmitting part there is apparatus which measures the mean power of the white noise passed to the element under test.

The main elements of the receiving part are (Figure 2): an attenuator; an amplifier; band-pass filters and an indicator. The number and the mid-frequencies of the band-pass filters correspond to the number and mid-frequencies of the blocking filters in the transmitter. Initially, the

Card2/5 entire white noise spectrum is applied to the element under

SOV/106-59-4-7/13
Use of White Noise for Measurement of Interference in the Telephone Channels of Radio-relay Lines

test. With the attenuator set to its maximum reading, the indicator reading is noted. The corresponding filters are switched in. This suppresses a small band of frequencies from the transmitter, but passes the same small band from the element to the indicator. The attenuator is reduced until the initial reading is again obtained on the indicator. The difference in the attenuator readings gives the increase of the white noise power in the band of the filters over the total power of the fluctuation and non-linear noise produced by the element in the same frequency band.

A basic disadvantage of this method is that the data have to be processed to obtain the form required by the MKKR recommendations. The author then describes a modification to the apparatus to overcome this disadvantage. A generator of sinusoidal signals is introduced into the transmitter (Figure 3). The method of measurement differs from the first in that, initially, a sinusoidal signal is applied to the input to the element under test, the frequency of the signal being the mid-frequency of the filters. The level of the signal is equal to the measured

Card3/5

SOV/106-59-4-7/13

Use of White Noise for Measurement of Interference in the Telephone Channels of Radio-relay Lines

level of one telephone channel at the input to the element. The white noise is applied to the element with a small band suppressed and the level of the white noise is equal to the level of the multi-channel signal. The results are obtained as in the previous case. By adding to the measured values 2.5 dB to account for the curve of the psophometer filter, the value of the increase of a sinusoidal signal over the psophometric noise is obtained. Whence the psophometric noise power relative to the zero level can be determined by:

$$P_{\omega n} = 10^{\frac{90-(p+2.5)}{10}} = 10^{\frac{87.5-p}{10}} \quad (3)$$

where p is the value of the excess of the sinusoidal signal over the power of the total noise. By using this formula, graphs can be constructed from which the psophometric noise can be easily obtained.

Card4/5

SOV/106-59-4-7/13

Use of White Noise for Measurement of Interference in the Telephone Channels of Radio-relay Lines

The author then gives brief details of apparatus designed for measurement of the relative noise power in radio-relay lines having 24, 60, 240 and 600 channels. Results of experimental checks on the apparatus are also given. There are 5 figures, 1 table and 5 references, 4 of which are Soviet and 1 English.

TITLE: Investigation of ferrite magnetization reversal over a nonhysteresis curve

SOURCE: Vsesoyuznoye soveshchaniye po ferritam i po beskontaktny*m magnitny*m elementam avtomatiki. 3d, Minsk. Ferrity* i beskontaktny*ye elementy* (Ferrites and non-contact elements); doklady* soveshchaniya. Minsk, Izd-vo AN BSSR, 1963, 234-239

TOPIC TAGS: ferrite, ferrite magnetization, magnetization reversal, magnetization curve, ferrite core, core storage

ABSTRACT: In a study of ferrite magnetization reversal, the authors discuss ideal or non-hysteresis magnetization curves created by the superimposition of weak stable and strong variable damping fields. A $2 \times 1.5 \times 1$ mm BT-1 core and a $3 \times 2 \times 1$ mm BT-5 core with coercive forces of 1.2 e and 0.3 e, respectively, and 3 coils were used in the experimental demonstration of the curves. Pulses were sent through 2 coils, as shown in the Enclosure, and the signal was read from the third. The coincident damping sine-shaped and steady-amplitude pulses magnetize the core in one direction while the other pulse of the opposite polarity reinstates it. To achieve complete magnetization reversal, the magnitude of the

Card 1/3

ACCESSION NR: AT4035415

two first damping half-periods must be sufficiently great and the period length $T > 2 T_{\text{per}}$.
This method of magnetization reversal may be useful in operative storage design and operation. Orig. art. has: 5 figures and 2 formulas.

III. PHYSICAL PROPERTIES OF LIQUID METALS AND SLAGS

Popov, S.P. and O.A. Fein. Methods of Measuring the Surface Tension of Liquid Metals and Slags 237

The authors describe the methods of measuring the surface tension of liquid metals and slags. The results obtained in measuring the surface tension of the system $\text{CrO-SiO}_2\text{-Al}_2\text{O}_3$ and $\text{CaO-SiO}_2\text{-MgO}$ by the method of the sessile-drop method and the method of the capillary tube are presented. The results of the measurements of the surface tension of the system $\text{CrO-SiO}_2\text{-Al}_2\text{O}_3$ lead to an increase in surface tension with an increase in the content of Al_2O_3 (with a constant ratio of CrO to SiO_2) also results in higher surface tension. This is explained by a breaking-down of silicate anions. It was shown that the replacement of CaO by MgO in the system $\text{CaO-SiO}_2\text{-MgO}$ has practically no effect on surface tension.

TITLE: On the Diagrams of State of the System Chromium-Niobium
(O diagramme sostoyaniya sistemy khrom-niobiy)

PERIODICAL: Metallovedeniye i Obrabotka Metallov, 1958, No.1
pp. 11 - 16 (USSR).

ABSTRACT: Use of niobium as an addition to chromium alloys has created an interest in the system chromium-niobium. However, very little data are published in literature on this system. Therefore, the authors investigated the manufacture by smelting and sintering of chromium alloys with niobium for the purpose of constructing the elements of the diagram of state of this system. The molten alloys were produced in a high-frequency furnace under a protective argon atmosphere from powders of electrolytic Cr-Nb of the sizes of 1 - 5 μ . The chromium was crushed in a steel ball mill and the iron removed by washing with nitric acid and then passed through a sieve with 10 000 holes/cm². The niobium powder contained 98.2% Nb, 0.93% Fe, 0.34% Ti, 0.06% Al, 0.56% Ca, 0.007% B and less than 0.01% P. The powders were mixed and pressed into briquettes, applying a pressure of 5 tons. A sketch of the melting device is given in Fig.1, p.11. The results of the thermal analysis

Card1/3

129-1-3/14

On the Diagram of State of the System Chromium-Niobium.

are entered in Table 1, p.12. The compositions of the obtained sinter alloys are entered in Table 2, p.12; Table 3, p.15, gives the results of the decoding of the X-ray picture of the inter-metallic compound (containing 47.3% Nb); Table 4 gives the results of measuring the parameters of the lattice of a chromium-base solid solution. In Figs. 2 - 8, a few of the obtained micro-photographs are reproduced. The data given in Table 3 indicate that almost all the lines of the X-ray pictures are in agreement with the assumptions made by the authors. The diagram of state of the system Cr-Nb proposed by the author, is plotted in Fig.9, p.16. The following conclusions are arrived at: on the basis of the results of thermal, metallographic and X-ray structural analysis and measurement of the micro-hardness, it was found that in the system Cr-Nb, only one inter-metallic compound NbCr_3 forms, which has a face-centred cubic lattice; inter-metallic compounds form eutectics with chromium- and niobium-base solid solutions and the temperature of eutectoidal crystallisation of the inter-metallic with chromium-base solid solution is 1660°C (for a content of about 31 wt.% Nb) and the second eutectic point is at 1710°C for a content of 66 wt.% Nb. Primary niobium- and chromium-base

On the Diagram of State of the System Chromium-Niobium. 129-1-3/14

solid solutions form; the solubility of niobium in chromium at 1 350 °C is about 3 wt.%. Long duration annealing at 1 350 °C coarsens the components of the eutectic and after annealing for 100 hours at 1 350 °C, the structure does not have a eutectoidal character. Alloys of chromium with niobium can be obtained by sintering inside a protective atmosphere at 1 550 °C; in the case of sintering for 2 to 5 hours at 1 550 °C, a full recrystallisation takes place and an equilibrium state is reached. There are 9 figures and 4 tables and 3 non-Slavic references.

TABLE OF CONTENTS:

Samsonov, G.V., and V.S.Neshpor. Some Physical Characteristics of Metal-like Compounds. 3

The authors describe results of investigations of microhardness, coefficient of thermal expansion, calculation of the inter-atomic bond between the metal and the metalloid, and factors affecting this bond. They conclude that the hardness of the metal-like compounds is determined chiefly by the bonding forces between the atoms of the metal and the metalloid.

ABSTRACT:

In the present paper the phosphorescence spectra of alcoholic solutions of pyrocatechol, resorcin, and hydrochinone were investigated at temperatures of liquid oxygen. The substances were selected because of the regular variation of their structure. The molecules are in the metastable state. The pictures were taken by means of a single-disk phosphoroscope. Spectra are illustrated by a figure from which it may be seen that isomerism influences the character of the spectra in that pyrocatechol and resorcin with the hydroxyl group in ortho-or meta-position, have a sharply marked structure, whereas hydrochinone, with the hydroxyl group in para-position, possesses only a band with a maximum at 427 mμ. <p>Calorization of low-carbon steel. N. A. Minichev and V. P. Sadler. <i>Vestnik Metalloprov.</i> 19, No. 8, 67-79 (1989).—Rods of low-C steel (0.07-0.16% C) 12 mm. in diam. and 22 mm. long were cleaned with 15% hot H₂SO₄ soln., covered with cementing salts. In Fe boxes and kept in gas furnaces for 3, 6 and 12 hrs. at 900, 975, 1050 and 1200°. The boxes were cooled in the furnace to 800° and then in the open to 100-200° before the specimens were removed. Twelve different calorizing mixes, contg. various amts. of NiAlCl, powders of Al, alumina, kaolin, quartz sand, or Al-Fe-Cu alloys were used. Best results from the point of view of cost and oxidation resistance (1200°) were obtained with the mixt. contg. 0.8% NiAlCl and 99.2% of Fe-Al-Cu alloy powder (42.2% Fe and 2.2-2.4% Cu). The temp. in the boxes should not be kept below 975° or 1050° depending upon the specific requirements. At lower temps. the rate of calorization is too slow and at higher temps. the structure becomes large-grained. The surface layers of the treated rods consisted of various phases of Fe-Al alloys depending upon their compn. Data on the rate of diffusion of Al and the resistance of the specimens to temps. of 800, 1050 and 1200° for the various calorizing mixes. are tabulated. R. Z. Kamich</p>

 Izvest. Akad. Nauk S.S.S.R., Otdel, Tekh. Nauk 1950, 108-25

App. is described for heating polished steel specimens of 25 sq. mm. cross-section up to the m.p. in vacuo (10⁻⁶ mm. Hg) and etching at the desired temp. by admitting Cl, HCL, HNO₃, N oxides, or air to several mm. Hg pressure. Heating is accomplished by passing elec. current through the specimen, and the temp. is detd. by thermocouples welded to the specimen. Above 900° the specimens are etched in vacuo because of the varying rate of vaporization of the phases and impurities present. Special attachments permit measurement of Vickers hardness at temp. up to 900° and of the rate of vaporization of the metal.

TITLE: Properties of ferrite aluminum-iron alloys

SOURCE: AN SSSR. Institut metallurgii. Trudy*, no. 14, 1963. Metallurgiya,
metallovedeniye, fiziko-khimicheskiye metody* issledovaniya, 68-77

TOPIC TAGS: aluminum alloy, iron alloy, aluminum-iron alloy, ferrite alloy, melting,
forging, heat treatment

ABSTRACT: Some properties of aluminum-iron alloys are of industrial importance, but they are not commonly used as construction materials. In the present work a number of these alloys were exposed to melting, forging and heat treatment, after which they were studied for specific gravity, impact strength, rupture strength and plasticity under various conditions. The chemical composition of the alloys used in the investigation is given in Table 1 of the Enclosure. Two series of alloys were melted: one group in air and the other in a vacuum. It was found that vacuum melting of the alloy improves the mechanical properties, especially under high-temperature conditions. Figure 1 of the

Cord 1/6

ACCESSION NR: AT4009495

Enclosure shows the dependence of the rupture strength and plasticity of the alloy on the aluminum content. The curves show that an increase in the aluminum content to about 15% increases the strength of the alloy between 20-600C; at 700C the strength does not depend on the aluminum content. The alloy has a maximum strength and satisfactory plasticity at 400C; the strength drops sharply and the plasticity simultaneously increases at temperatures over 600 C. Aluminum-iron alloys may thus be used under stress without adding a third element at temperatures below 600C. Figure 2 of the Enclosure shows that an increase in the aluminum content in the alloy increases grain size at 1,100C. Additional studies on the effect of admixtures (Ti, Zr, B, Ni, W) on the properties of the Al-Fe alloys shows that the introduction of titanium, zirconium, and boron into alloys with 10% Al does not change the strength of the alloy. Zirconium and boron lower the scaling resistance of the alloy while additions of nickel and tungsten to an alloy with 15% Al lowers the strength and plasticity of the alloy. Orig. art. has: 7 figures and 6 tables.

TITLE: "Chromium-manganese-aluminum austenite steel

SOURCE: AN SSSR. Institut metallurgii. Issledovaniya po zharoprochnym splavam, v. 10, 1963, 144-148

TOPIC TAGS: steel, austenite steel, chromium-manganese-aluminum steel, austenite steel magnetic property, steel strength carbon content dependence.

ABSTRACT: Austenitic steels with an Fe-Cr-Mn base are finding an ever-widening range of industrial application. The authors point out that the alloying of chromium-manganese steel with carbon and aluminum yields a satisfactory complex of strength properties at both normal and high temperatures. This paper gives the results of a study of the mechanical properties, as well as certain other properties, of chromium-manganese-aluminum steel. The study was based on an alloy of 9-10% Cr and 13-15% Mn, with a varying content of aluminum and carbon. Strength tests were made on IM-4P machines (tensile strength tests) and IP-5 machines (tests for creep and fatigue strength). The data obtained on short-term mechanical properties indicate that carbon definitely strengthens chromium-manganese-aluminum steel. An increase in plasticity results from increasing the amount of the plas-

tic structural component (austenite) in the steel. The maximum is attained with a carbon concentration which provides for a 100% austenitic condition. An increase in the carbon content from 0.5 to 0.9% has no effect on the notch toughness of the steel, after annealing at temperatures of 1050-1150C. At temperatures of 700-750C, steel containing approximately 3% Al has reduced creep resistance when the carbon content is increased over the amount necessary for the creation of a stable austenitic structure. In the initial condition (after annealing), all the steels were non-magnetic. The long-term effect of temperature and stress led to the formation of up to 34-36% ferromagnetic phase in steel with 10% Cr, 14% Mn, and 0.1%C. When the aluminum concentration was increased from 3 to 6%, the authors noted a considerable rise in the ultimate strength value. This rise results from a certain strengthening of the austenite and from a considerable reduction of the grain that occurs with the appearance of small quantities of ferrite phase. In the fatigue-strength test, failure time was shortened drastically as the aluminum concentration was increased. A sample of austenitic steel with 3% Al did not fracture after 6000 hours of testing, and the total deformation was less than 1.1%. In the case of steel with 4.5% Al, the austenite partially decays under the influence of high temperature deformation. Although this steel was non-magnetic prior to the test, it was found to be about 35% magnetic after a failure time of 134 hours. The authors conclude that it is possible to obtain a metal with satisfactory heat resistance by the aluminum-alloying of Fe-Cr-Mn-C austenitic steel. However, the aluminum con-

tent must not exceed that which causes the appearance in the structure of a fer-
rite component, either in the initial (tempered) state, or after an extended ex-
posure to high temperatures and stress. It was also noted that an addition of
6-8% aluminum reduces the density of Cr-Mn steel by about 10-12%. Orig.

TITLE: Investigation of the phase composition of chromium-manganese-aluminum steel

SOURCE: AN SSSR. Institut metallurgii. Issledovaniya po zharoprochny*m splavam, v. 10, 1963, 138-143

TOPIC TAGS: steel phase composition, steel, chromium alloy, manganese alloy, aluminum alloy, steel property carbon dependence

ABSTRACT: Chromium-nickel austenite steels are being replaced by chromium-manganese steels, both in the SSSR and in other countries. The influence of carbon (0.1-0.8%) and aluminum (3-7.5%) on the position of the α , ($\alpha + \gamma$) and γ phases for steel with 10% Cr and 14% Mn was investigated at 800, 950, 1100 and 1250C. It was shown that the content of the ferro-magnetic phase in the steel increases in direct proportion to the aluminum concentration (for constant carbon content) and decreases as the carbon content increases (for a constant aluminum content). The top concentration of aluminum in the austenite rises together with an increase of carbon in the steel. The carbon concentration required for complete change of the α -crystalline lattice into γ

Card 1/2

ACCESSION NR: AT4013939

remains practically the same when the aluminum content in the steel changes. The effectiveness of aluminum for α -formation is lowered and that of carbon for α -formation increases as the temperature rises. Using metallographic analysis, it can be shown that the diffusion temperature of carbides rises with an increase in the aluminum and carbon content. Orig. art. has: 5 figures and 2 tables.

Influence of quenching temperature on the formation of the δ -phase in chromium-manganese steel (18 % Cr, 14 % Mn)

Akademiya nauk SSSR. Institut metallurgii. Issledovaniya po zharoprochnym splavam. v. 7, 1961, 159 - 168

TEXT: Yu.I. Kiselev participated in the experimental work. A steel of the following chemical composition was studied: 0.07 % C, 0.53 % Si, 13.91 % Mn, 18.59 % Cr, 0.03 % N, 0.009 % S and 0.032 % P. This was melted in an induction furnace. The ingot (12 kg) was forged into cylindrical billets of 12 mm diameter. These were water quenched from 1100° and 1200°C. The quenched metal was tempered in the interval 500 - 900°C for period of 10 minutes to 130 hours. The change in hardness and microhardness of a steel containing the ferromagnetic phase, and the microstructures after tempering were studied; an X-ray analysis was also carried out. It was found, that

ter quenching from 1100°C, the σ -phase forms directly from the ferrite on tempering. In X-ray pictures taken of specimens after quenching from 1100°C and tempering for various periods of time, lines for ferrite, austenite and the FeCr-type σ -phase were obtained. The hardness of the steel is directly proportional to the quantity of decomposed ferrite. After quenching from 1200°C, the formation of σ -phase from ferrite during tempering passes through intermediate stages. In the first stage 'excess' austenite precipitates from the ferrite. The change in hardness of the steel is not directly proportional to the ferrite content. There are 6 figures, 2 tables and 12 references: 4 Soviet-bloc and 8 non-Soviet-bloc.
